Population: describes the sum total of all *existing* values of a variable given a certain research question. This includes non-measured data.

Sample: describes the sum total of al available values of a variable for any given analysis. This can only include measured data.

An example:

In an experimental set-up, you rear an ant colony of exactly 10,000 individuals You are interested in the average mandible strength of ants within the colony.

The problem: You cannot possibly take measurements of all 10,000 individuals.

Population: describes the sum total of all *existing* values of a variable given a certain research question. This includes non-measured data.

Sample: describes the sum total of al available values of a variable for any given analysis. This can only include measured data.

An example:

In an experimental set-up, you rear an ant colony of exactly 10,000 individuals. You are interested in the average mandible strength of ants within the colony.

The problem: You cannot possibly take measurements of all 10,000 individuals.

This differentiation is only applicable when concerned with modelling.

Training Data: describes the subset of the total data which is used to

Test Data: describes the subset of the total data which is used to *test* the performance of the model.

The problem: You have identified a way to model how mandible strength and ant size are interconnected but don't know how to assess the quality of your model (a model will always fit the data it was built on extremely well).

The solution: Split the available data into two non-overlapping subsets of data (**Training** and **Test Data**) and use these separately to build your model and assess its performance.

This differentiation is only applicable when concerned with *modelling*.

Training Data: describes the subset of Test Data: describes the subset of the the total data which is used to establish/train the model.

This differentiation is only applicable when concerned with *modelling*.

Training Data: describes the subset of Test Data: describes the subset of the the total data which is used to establish/train the model.

Randomisation is one of the **most important** practices in biological studies.

A **sampling** procedure is **random** when any member of the *population* has an equal chance of being selected into the *sample*.

Training and *Test Data Sets* are established from the population with the same sense of randomness although there may be exceptions depending on the modelling procedure at hand.

Data collection: Number all units contained within the set-up and sampl those units corresponding to random

Stratified Sampling

When do we break true randomness?.

When a **population** can be divided into distinct categories (i.e. **strata**). These can be regarded as individual sub-populations.

Stratified sampling ensures that all sub-populations are proportionally represented in the final population-sample given their relative size.

Stratified Sampling

When do we break *true* randomness?.

When a **population** can be divided into distinct categories (i.e. **strata**). These can be regarded as individual sub-populations.

Stratified sampling ensures that all sub-populations are proportionally represented in the final population-sample given their relative size.

```
set.seed(42) # stratified

## s Freq
    table(sample(d$s, replace = TRUE, prob = d$Freq, 100))

## 1 A 50  ##

## 2 B 35  ## A B C

## 45 38 17

set.seed(42) # non-stratified
    table(sample(d$s, replace = TRUE, 100))

##

## A B C
```

Stratified Sampling

When do we break true randomness?.

When a **population** can be divided into distinct categories (i.e. **strata**). These can be regarded as individual sub-populations.

Stratified sampling ensures that all sub-populations are proportionally represented in the final population-sample given their relative size.

Unsupervised methods are often *used to select* the *most informative X input* variables for supervised approaches.

→ "Pre-processing" before a supervised learning analysis and

Unsupervised methods are often *used to select* the *most informative X input* variables for supervised approaches.

Pre-requisites:

- Only input variables are observed.
- No solution/feedback (output) is given.

→ "Pre-processing" before a supervised learning analysis and

Unsupervised methods are often *used to select* the *most informative* X *input variables* for *supervised approaches*.

Pre-requisites:

- Only input variables are observed.
- No solution/feedback (output) is given.

Aims:

- Divide the observations into relatively distinct groups.
- Model the underlying structure or distribution in the data.

ightarrow "Pre-processing" before a supervised learning analysis and exploratory analyses

Unsupervised methods are often *used to select* the *most informative* X *input variables* for *supervised approaches*.

Pre-requisites:

- Only input variables are observed.
- No solution/feedback (output) is given.

Aims:

- Divide the observations into relatively distinct groups.
- Model the underlying structure or distribution in the data.

 \rightarrow "Pre-processing" before a supervised learning analysis and exploratory analyses

Supervised methods are often *informed by unsupervised approaches* and used to *gain validated information* about the data.

Pre-requisites:

- Both predictors X, and responses Y are observed (there is one y_i for each x_i).
- Data is split into Training and Test Data Sets.

ightarrow Mostly inferential analyses

Aims:

- Learn a mapping function f from X to Y.
- Validate established function/model.
- Further prediction and inference.

Supervised methods are often *informed by unsupervised approaches* and used to *gain validated information* about the data.

Categorical Variables

Categorical variables are those variables which **establish and fall into distinct groups and classes**.

Categorical variables

- can take on a finite number of values
- assign each unit of the population to one of a finite number of groups
- can sometimes be ordered

In R, categorical variables usually come up as object type factor or character.

Continuous Variables

Continuous variables are those variables which **establish a range of possible data values**.

Continuous variables:

- can take on an infinite number of values
- can take on a new value for each unit in the set-up
- can always be ordered

In R, continuous variables usually come up as object type numeric.

Continuous variables can be converted into categorical variables via a method called **binning**:

Given a variable range, one can establish however many "bins" as one wants. For example:

- Given a temperature range of 271K 291K, there may be 4 bins of equa size:
 - Bin A: 271K < X < 276K
 - Bin B: 276K < X < 281K
 - Bin C: $281K < X \le 286K$
 - Bin D: $286K < X \le 291K$

Continuous variables can be converted into categorical variables via a method called **binning**:

Variable scales include:

- Nominal
- Binary
- Ordinal

- Interval
- Relation/Ratio

Nominal scales of variables correspond to *categorical variables* which cannot be put into a meaningful order.

- Variables on nominal scales put units into distinc categories
- These variables may be numerical but offer no mathematical interpretation

Examples:

- Petal colour (red, green, blue, etc.)
- Individual IDs

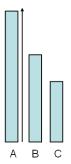

Nominal scales of variables correspond to *categorical variables* which cannot be put into a meaningful order.

- Variables on nominal scales put units into distinct categories
- These variables may be numerical but offer no mathematical interpretation

Examples:

- Petal colour (red, green, blue, etc.)
- Individual IDs

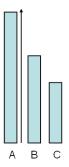

Nominal scales of variables correspond to *categorical variables* which cannot be put into a meaningful order.

- Variables on nominal scales put units into distinct categories

Ordinal

Ordinal scales of variables correspond to *categorical variables* which can be put into meaningful order.

- Variables on ordinal scales put units into distinct categories
- These variables may be numerical and offer some mathematical interpretation

Examples:

- Size (small, medium, large, etc.)
- Binned continuous variables

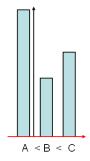

Ordinal

Ordinal scales of variables correspond to *categorical variables* which can be put into meaningful order.

- Variables on ordinal scales put units into distinct categories
- These variables may be numerical and offer some mathematical interpretation

Examples:

- Size (small, medium, large, etc.)
- Binned continuous variables

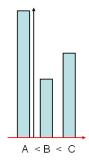

Ordinal

Ordinal scales of variables correspond to *categorical variables* which can be put into meaningful order.

- Variables on ordinal scales put units into distinct categories
- These variables may be numerical and offer some mathematical interpretation

Examples:

- Size (small, medium, large, etc.)
- Binned continuous variables

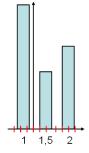

Interval/Discrete

Interval scales of variables correspond to a mix of continuous variables.

- Variables on interval scales are measured on equal intervals from a defined zero point/point of origin
- The point of origin does not imply an absence of the measured characteristic

Examples.

- Temperature [$^{\circ}C$]
- pH

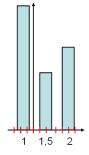

Interval/Discrete

Interval scales of variables correspond to a mix of continuous variables.

- Variables on interval scales are measured on equal intervals from a defined zero point/point of origin
- The point of origin does not imply an absence of the measured characteristic

Examples.

- Temperature [$^{\circ}C$]
- pH

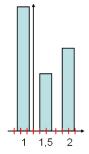

Interval/Discrete

Interval scales of variables correspond to a mix of *continuous variables*.

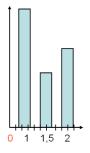

- Variables on interval scales are measured on equal intervals from a defined zero point/point of origin
- The point of origin does not imply an absence of the measured characteristic

Examples:

- Temperature [°C]
- pH

Relation/Ratio scales of variables correspond to continuous variables.

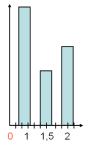

Relation/Ratio scales of variables correspond to continuous variables.

- Variables on relation/ratio scales are measured on equal intervals from a defined zero point/point of origin
- The point of origin does imply an absence of the measured characteristic

- Temperature [K]
- Weight

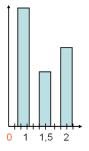

Integer scales are a special case of ratio scales allowing only for integral numbers.

Relation/Ratio scales of variables correspond to continuous variables.

- Variables on relation/ratio scales are measured on equal intervals from a defined zero point/point of origin
- The point of origin does imply an absence of the measured characteristic

- Temperature [K]
- Weight

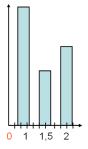

Integer scales are a special case of *ratio scales* allowing only for integral numbers.

Relation/Ratio scales of variables correspond to continuous variables.

- The AUC between two values on the X-axis equals the probability to randomly sample a value between these two points

Probability Density Distributions hold the **majority of importance** in statistics!

- Area under the curve (AUC) sums to 1
- A probability for every given single value is 0
- The AUC between two values on the X-axis equals the probability to randomly sample a value between these two points

- Used to represent real-value random variables whose distributions are not known
- The central limit theorem applie (draw a sufficient number of samples and you end up with the normal distribution)
- These distributions are usually known also as "bell curves"
 (Attention: other distributions take this shape too)

- Used to represent real-valued random variables whose distributions are not known
- The central limit theorem applie (draw a sufficient number of samples and you end up with the normal distribution)
- These distributions are usually known also as "bell curves"
 (Attention: other distributions take this shape too)

Testing for normality of the data is crucial for certain statistical procedures.

Testing for normality of the data is **crucial** for certain statistical procedures.

The Shapiro-Wilks Test In Theory The QQ Plot In Theory

Testing for normality of the data is **crucial** for certain statistical procedures.

The Shapiro-Wilks Test In Theory

- Base assumption: The data is normally distributed
- If p-value < chosen significance level, the data is **not** normally distributed
- Very sensitive to sample size

The QQ Plot In Theory

Testing for normality of the data is **crucial** for certain statistical procedures.

The Shapiro-Wilks Test In Theory

- Base assumption: The data is normally distributed
- If p-value < chosen significance level, the data is **not** normally distributed
- Very sensitive to sample size

The QQ Plot In Theory

- Method for comparing two probability distributions by plotting their quantiles against each other
- If the two distributions being compared are similar, the plot will show the line y = x.
- Compare the data distribution to the normal distribution

29 / 38

Using the shapiro.test() function:

```
shapiro.test(rnorm(5000, 20, 2))
##
## ## Shapiro-Wilk normality test
## ## Shapiro-Wilk normality test
##
## data: rnorm(5000, 20, 2) ## data: seq(1, 500, 5)
## W = 1, p-value = 0.7 ## W = 0.95, p-value = 0.002
→ Clearly a normal distributed set of values
Clearly no normal distributed set of values
```

For data sets bigger than 5000 data points, use the Kolmogorov-Smirnov test (ks.test()) in R.

Using the shapiro.test() function:

For data sets bigger than 5000 data points, use the Kolmogorov-Smirnov test (ks.test()) in R.

The Q-Q Plot

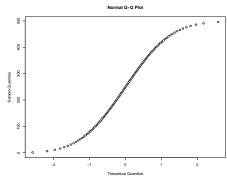

Using the qqnorm() function:

ggnorm (rnorm (5000, 20, 2))

→ Clearly a normal distributed set of values

ggnorm (seg (1, 500, 5))

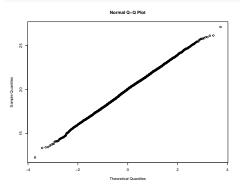

→ Clearly no normal distributed set of values

The Q-Q Plot

Using the qqnorm() function:

qqnorm(rnorm(5000,20,2))

ggnorm(seg(1,500,5))

Normal Q-Q Plot

→ Clearly a normal distributed set of values

→ Clearly no normal distributed set of values

Theoretical Quantiles

The Q-Q Plot

Using the qqnorm() function:

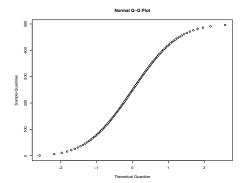

qqnorm(rnorm(5000,20,2))

Normal Q-Q Plot

 \rightarrow Clearly a normal distributed set of values

Theoretical Quantiles

qqnorm(**seq**(1,500,5))

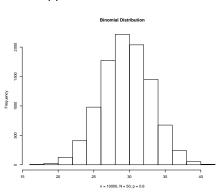

ightarrow Clearly no normal distributed set of values

One of the **more important** distributions. It is applicable to:

- Variables which can only take tw possible values (e.g. "states")
- All records of the variable have the same probability p of being in one of the two states

It is made up of three criteria

- p the "success" probability
- n sample size (how often we sample)
- N the "binomial total" (for how many individuals we sample each time)

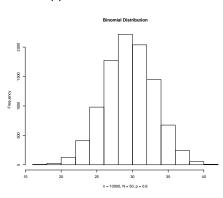

One of the **more important** distributions. It is applicable to:

It is made up of three criteria:

- p the "success" probability
- n sample size (how often we sample)
- N the "binomial total" (for how many individuals we sample each time)

Another one of the **more important** distributions. It is applicable to:

- Focal objects are placed randoml in one or more dimensions
- A random "counting window" (usually one considering time) is placed above the sampling scheme

t is made up of two **criteria**:

- λ the mean (= expectation, average count, intensity) as well as the variance (i.e., variance = mean)
- \blacksquare n sample size

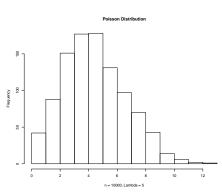

Another one of the **more important** distributions. It is applicable to:

- Focal objects are placed randomly in one or more dimensions
- A random "counting window" (usually one considering time) is placed above the sampling scheme

Skewness I

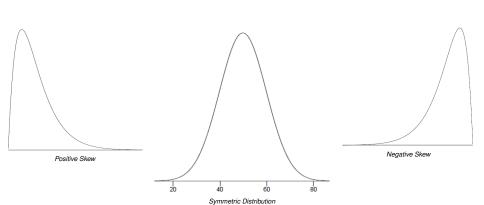

Definition: Describes the symmetry and relative tail length of distributions.

Positive skew: Right-hand tail is longer than the left-hand tail

Skew = 0: Symmetric distribution

Negative skew: Left-hand tail is longer than the right-hand tail

Skewness II

Kurtosis I

Describes the evenness/"tailedness" of distributions.

Positive kurtosis:

Short-tailed distribution aka. *leptokurtic*

Kurtosis = 0:

Base representation of a given distribution aka. mesokurtic

Negative

Long-tailed distribution aka. platykurtic

kurtosis:

Kurtosis II
